This is a link to start. A: You can use to create live streams. You can also use external app like Instagram Live, Facebook Live, etc. But you won't be able to save it. We've all seen comic books, television shows, and movies where a space villain has a devious plot to lure Earth heroes to a planetoid and blast them out of the sky. The problem is, one couldn't really accomplish such a thing. If someone was going to pull off such a feat, it would involve having more than one spacecraft. As this video demonstrates, once you start firing even one shot, you can end up getting quite a large number of objects. The number of orbits that you see depend on how much mass and energy you throw at the target. A collisional impact will alter the orbits of the objects, causing them to go into different orbits. While small asteroids go into tighter orbits, large asteroids can have hundreds of thousands of meters of diameters, and are not easy to alter an orbit. The video is mostly from NASA's Magellan mission, which used two spacecraft to test firing in space. The Magellan spacecraft consisted of a probe and a lander that were joined together by a rope. The probe fired its rocket first, and the lander was released on top of the probe. Once the probe was ejected, the lander separated from the probe, eventually being captured by a planet. The payload on Magellan was a laser altimeter. If you've never seen a laser altimeter in action, imagine taking a super-bright flashlight, and directing it towards a target at one mile. The laser shines through the target, and then bounces back to a laser receiver on the craft. If the target is moving, the laser receiver on the craft will be moving as well, and thus the craft's distance to the target will be changing. An optical telescope is able to determine the distance to a target by measuring how long it takes a laser pulse to bounce back to the receiver. With a laser altimeter, you could lock on to an object, and send a laser beam at it to measure the distance to the 82157476af
